MK 25/2500

MK 25/2500

SOLID STATE STEREO AMPLIFIER

SERVICE MANUAL

Components for the Connoisseur

Price \$2.00

SPECIFICATIONS MARK 25/2500

RMS (Min) CONTINUOUS POWER OUTPUT
PER CHANNEL 20Hz TO 20kHz (BOTH
CHANNELS DRIVEN) INTO 8 OHMS..... 300 Watts @ 0.05% Total Harmonic Distortion

THD (TOTAL HARMONIC DISTORTION)
FROM 20 Hz TO 20 kHz AT 250mW TO
RATED POWER AT 8 OHMS..... 0.05% Max.

IM (INTERMODULATION DISTORTION)
FROM 250mW TO RATED POWER AT
8 OHMS WITH ANY 2 MIXED FREQUEN-
CIES BETWEEN 20 Hz AND 20 kHz AT
4/1 VOLTAGE RATIO 0.05% Max.

FREQUENCY RESPONSE AT RATED
POWER +0.25dB, 20 Hz TO 20kHz

NOISE Greater than 100dB below rated power

TRANSIENT RESPONSE OF ANY
SQUARE WAVE 2.5 micoseconds rise and fall

SLEW RATE 40 Volts per microsecond

STABILITY Unconditionally stable with any type of load or no load
including full-range electrostatic loudspeakers

DAMPENING FACTOR 150 Min. (100Hz)

INPUT SENSITIVITY 1.84V RMS for rated output at 8 Ohms

INPUT IMPEDANCE 50K Ohms

SEMICONDUCTOR COMPLEMENT 46 transistors, 49 diodes

OVERLOAD PROTECTION 1. Low impedance electronic-sensing circuit limits with
output current below 2 Ohms without limiting with
4 Ohms or higher (or reactive loads).
2. Thermal sensing of inadequate ventilation
3. Internal B+, B- supply fuses.

LOUDSPEAKER PROTECTION Relay circuit protects loudspeakers from low frequency
oscillations and plus or minus D.C. output. Five second
turn on/off delay eliminates on/off disturbances.

POWER REQUIREMENTS 110-125V, 50Hz/60Hz 100 Watts @ idling to 1100
Watts @ rated output.

SHIPPING WEIGHT 68 pounds (30.9Kg)

DIMENSIONS Front panel: 19 in. (48.3cm) W x 7 in. (17.8cm) H
Chassis: 15.75 in. (40cm) D (excluding handles, controls
and connections).

WALNUT CABINET WC-25 (not included)

AMPLIFIER REPAIR HINTS

MK 25/2500

DISASSEMBLY:

- 1) To remove top cover, unscrew 16 screws (6 on top, 3 on each end, and 4 on rear).
- 2) To remove the amp module, unscrew 13 screws: 3 on the bottom of the chassis, and 5 on either side. Remove 4 slip terminal leads on fuse blocks going to amp module, unscrew bridge rectifier, unscrew amp module ground wires from capacitor ground bus, unplug gain and meter wires, and unscrew thermal switch leads from AC terminal block.
- 3) The transistor covers may be removed by unscrewing fan (2 screws on inside and 2 on rear of heatsink), remove AC plug from fan, and unscrew 6 screws on transistor covers.
- 4) The drive board may be removed by unscrewing 2 screws fastening to heatsink assembly.
- 5) The pre-drive board may be removed by unscrewing 2 screws, and unplug input and gain wires.
- 6) The relay board may be removed by 1 thumb screw.

REPAIRING:

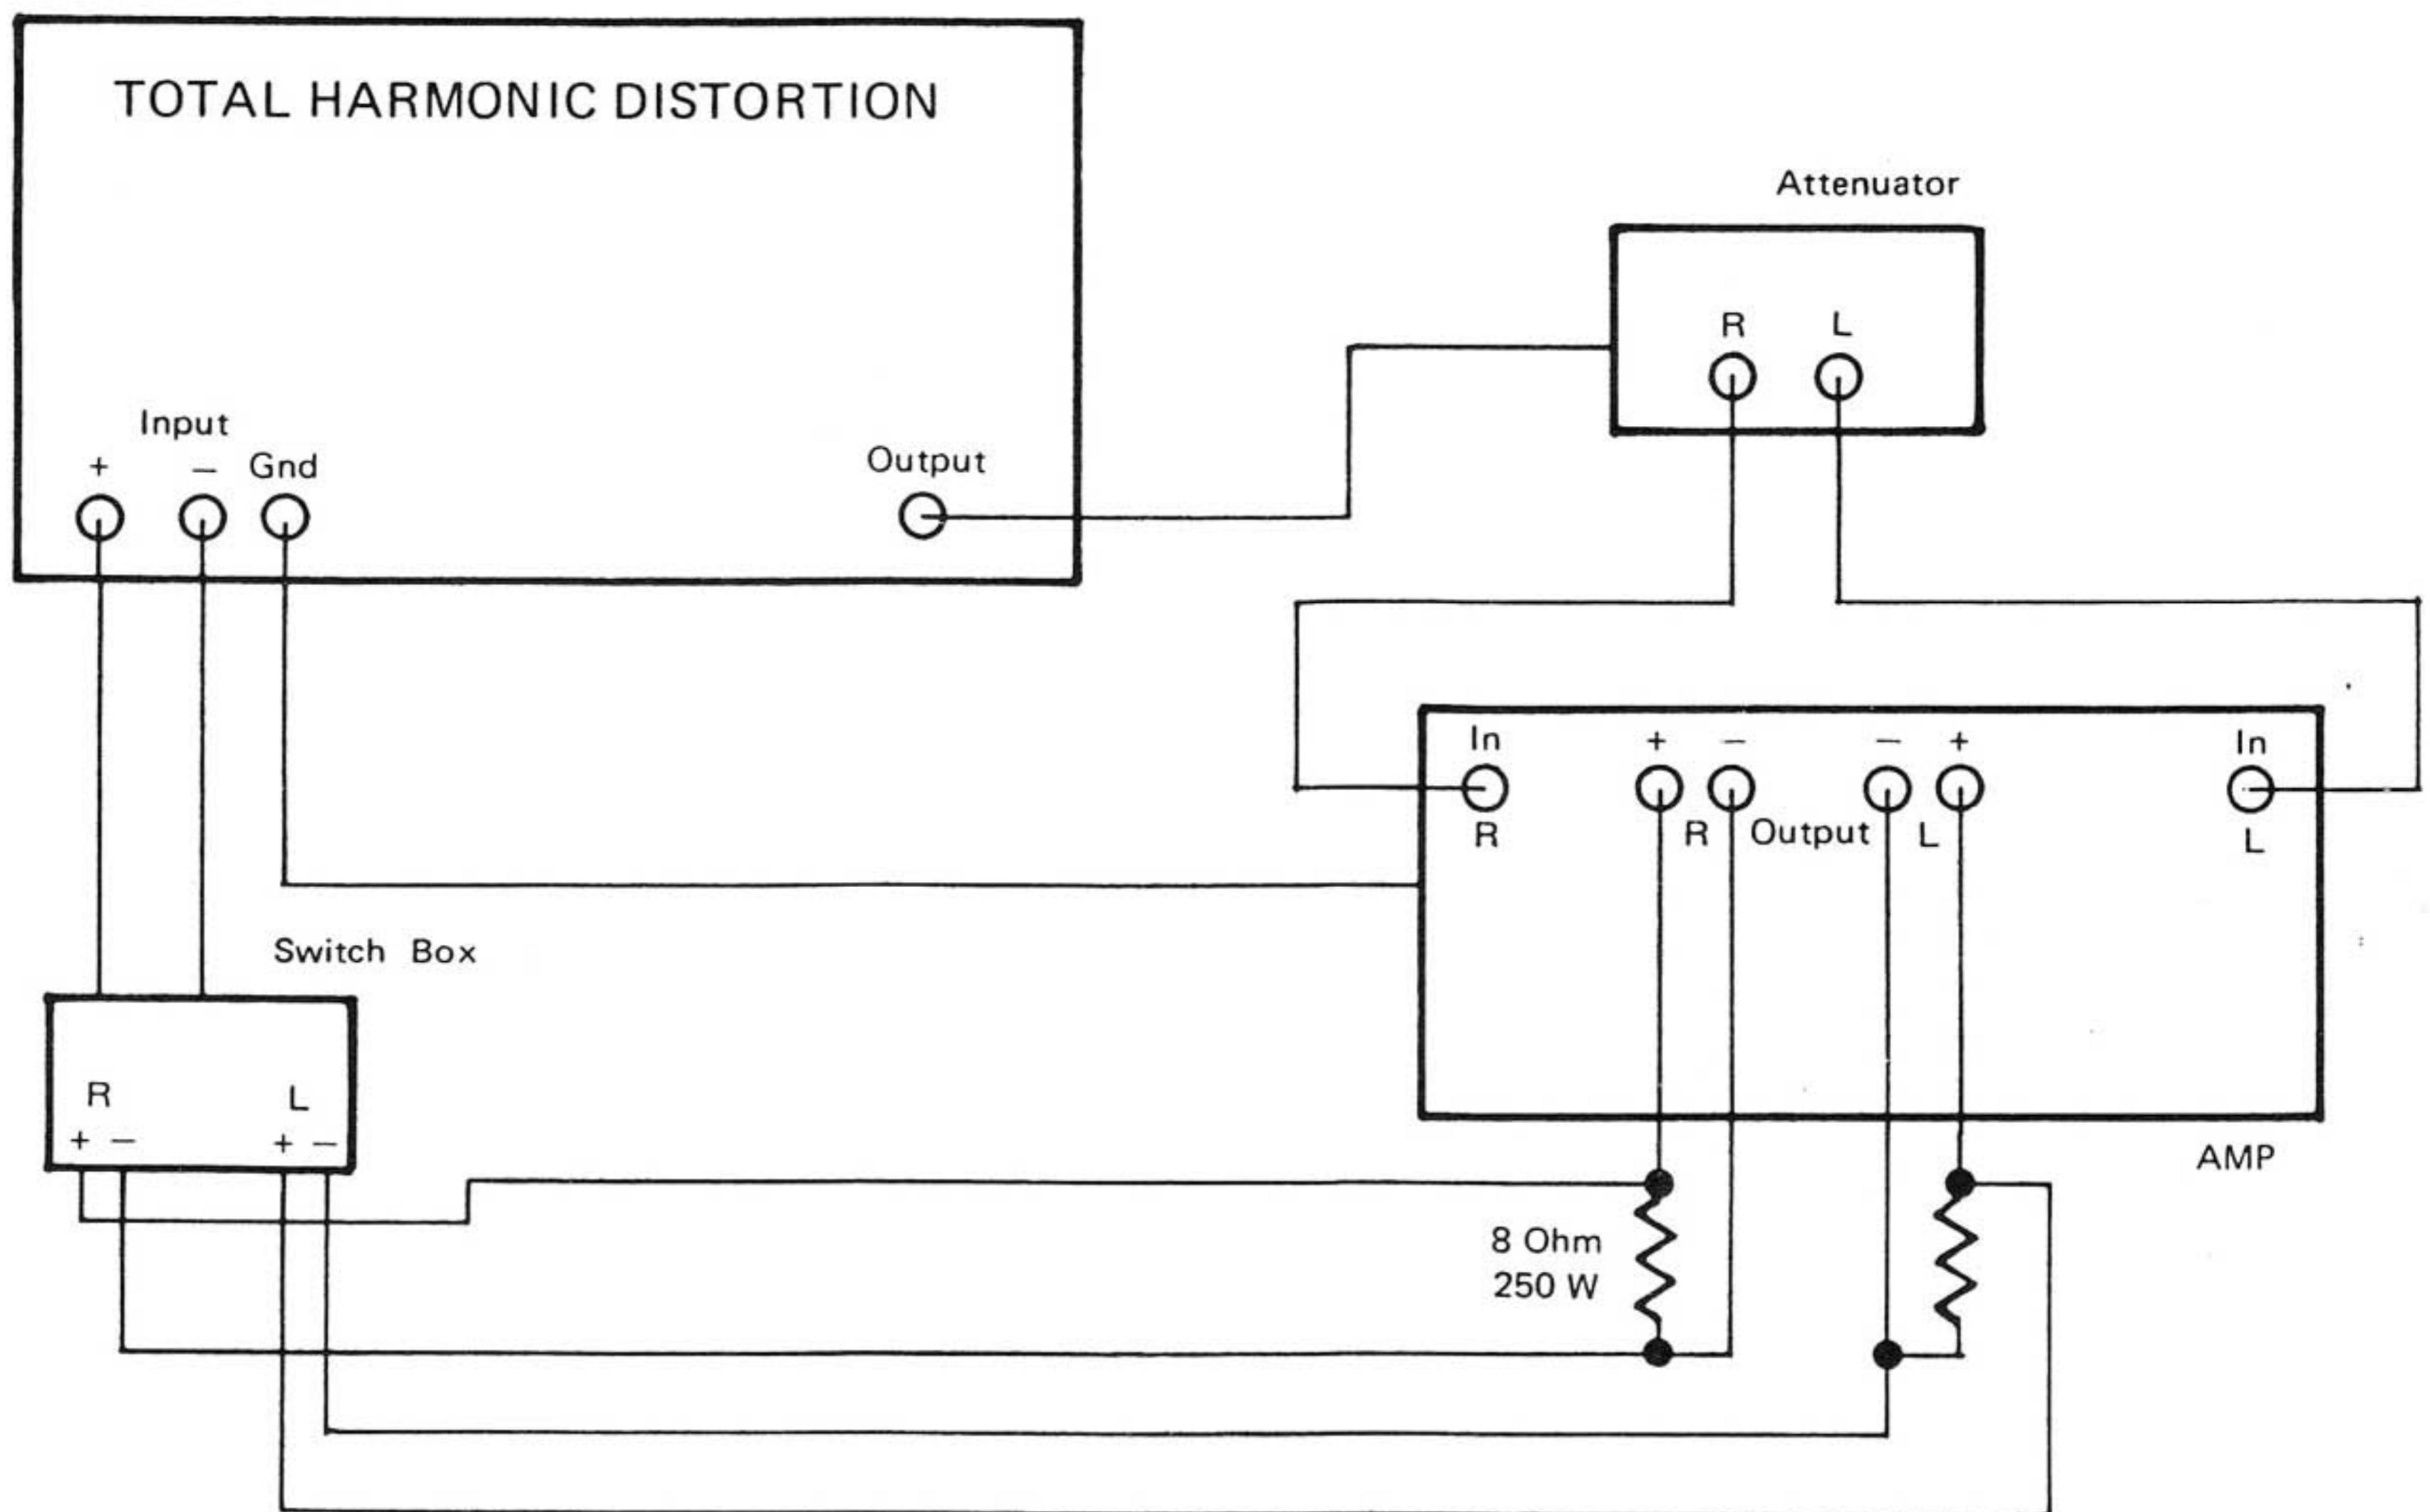

- 1) If the amplifier is not operating properly or blew the B supply fuses or blew the power fuse, use an Ohmmeter to measure the resistance from the NPN output transistor collector(s) (Q20, Q21) to the output before the relay at the output choke (L3) of the appropriate channel. When making this measurement connect the positive lead of the Ohmmeter to the output coil (L3) and have all boards inserted in module. These readings should be higher than 3K Ohms for the inside transistor(s) (Q22, Q23), and higher than 1.8K Ohms for the slave transistor(s) (Q20, Q21). If any of these resistance readings is less than 3K Ohms or 1.8K Ohms, it is likely that the driver transistor(s) or output transistor(s) is defective and should be replaced. Repeat with the PNP output transistors, but this time connect the positive lead of the Ohmmeter to the transistor collector case (Q26 or Q27).
- 2) To evaluate the condition of the bias regulator, short the input jacks and monitor the D.C. voltage across the regulator by measuring from collector-to-collector of the driver transistors (Q1, Q3). If the voltage is greater than 2.25V then the regulator is probably open and should be replaced. Also see that the regulator voltage can be adjusted with the control (R61) on the bottom of the PC board from a minimum of 1.5V to a maximum of 2.25V. This D.C. voltage should not exceed 2.25V when the amplifier is operated with full-line voltage. When a circuit malfunction is suspected, use a Variac to apply only 10% (approx.) of the full supply voltage (12-15V) to check for this condition. Also check the pre-driver transistor condition as described in step 3 below.
- 3) Check for burned resistors on the Pre-drive circuit board, especially the 62 Ohm resistors (R35, R36) and the 10 Ohm resistors (R30, R31). If any resistors appear faulty, then use an Ohmmeter to check the condition of the driver stages (Q1, Q3, Q5, Q7) and the protection stages (Q2, Q4) for either collector-to-emitter or base-to-collector shorts (each resistance reading should exceed 500 Ohms). If any resistance reading is unreasonably low, replace the faulty transistor.

- 4) With no output load on the amplifier, increase the supply line voltage to rated voltage. Now measure the amplifier output D.C. offset voltage. This voltage should be zero, if not, check to see that the D.C. offset adj. (R37) is properly adjusted. If this adjustment does not correct the problem, first check the 10 Ohm ground resistors (R34) to see if they are open. If defective, replace this resistor. If excessive offset voltage still persists, check the input differential-amplifier pair (Q9, Q10, Q11, Q12), the D.C. level shifters (Q6, Q8) and associated diodes (D5, D6) to verify that none are defective. After correcting the problem, go back and readjust the D.C. offset adjust (R37) for zero voltage on the amplifier-output terminals.
- 5) Check each output transistor for proper series voltage division. The outside pairs should read +95V on collector(s) (Q20, Q21), -95V on collector(s) (Q26, Q27), +47.5V on collector(s) (Q22, Q23), and -47.5V on collector(s) (Q24, Q25). If these voltages on Q22, Q23 or Q24, Q25 are not 1/2 of the supply voltage (+95V), check for faulty driver transistors (Q13, Q14, Q15, Q16), voltage dividing resistors (R39 thru R47) or capacitors (C26, C27, C31, C32).
- 6) Carefully check the D.C. quiescent current adjustment by measuring with a Voltmeter from +95V supply to collector of the protection transistor (Q4). It should read 2.1V which is equivalent to a current of 30mA. If not, readjust the Quiescent Current Adj. (R38) for proper reading. If the current is low, and not adjustable, first check the Zener diode (D11) for 51V. If this voltage is correct, check both differential transistor pairs one at a time. After the fault is corrected, recheck quiescent current. Adjust R38 if necessary.
- 7) Adjust the output-transistor bias control (R61) for 2.1V D.C. measured from collector-to-collector of the driver transistors (Q1, Q3). If possible, the bias should also be re-adjusted to achieve between .03% to .04% harmonic distortion at 20KHz with an 8 Ohm load at 1 Watt (2.8V RMS) output.
- 8) When replacing output transistors, care must be taken that silicone heat-transfer compound (20-0045) is applied to both sides of the plastic or mica transistor insulator (18-0075). Only a thin film is required; however, it is important that the entire surface area is covered. It is also important that the area beneath the transistor be kept clean (except for the heat compound) so that there are no foreign objects such as metal filings which might puncture the plastic insulator. Finally, tighten the output transistor securely to the heatsink. To insure that the heat sink performs its heat-transfer function properly, retighten the transistor screws after the amplifier has been allowed to become warm after operating under power.

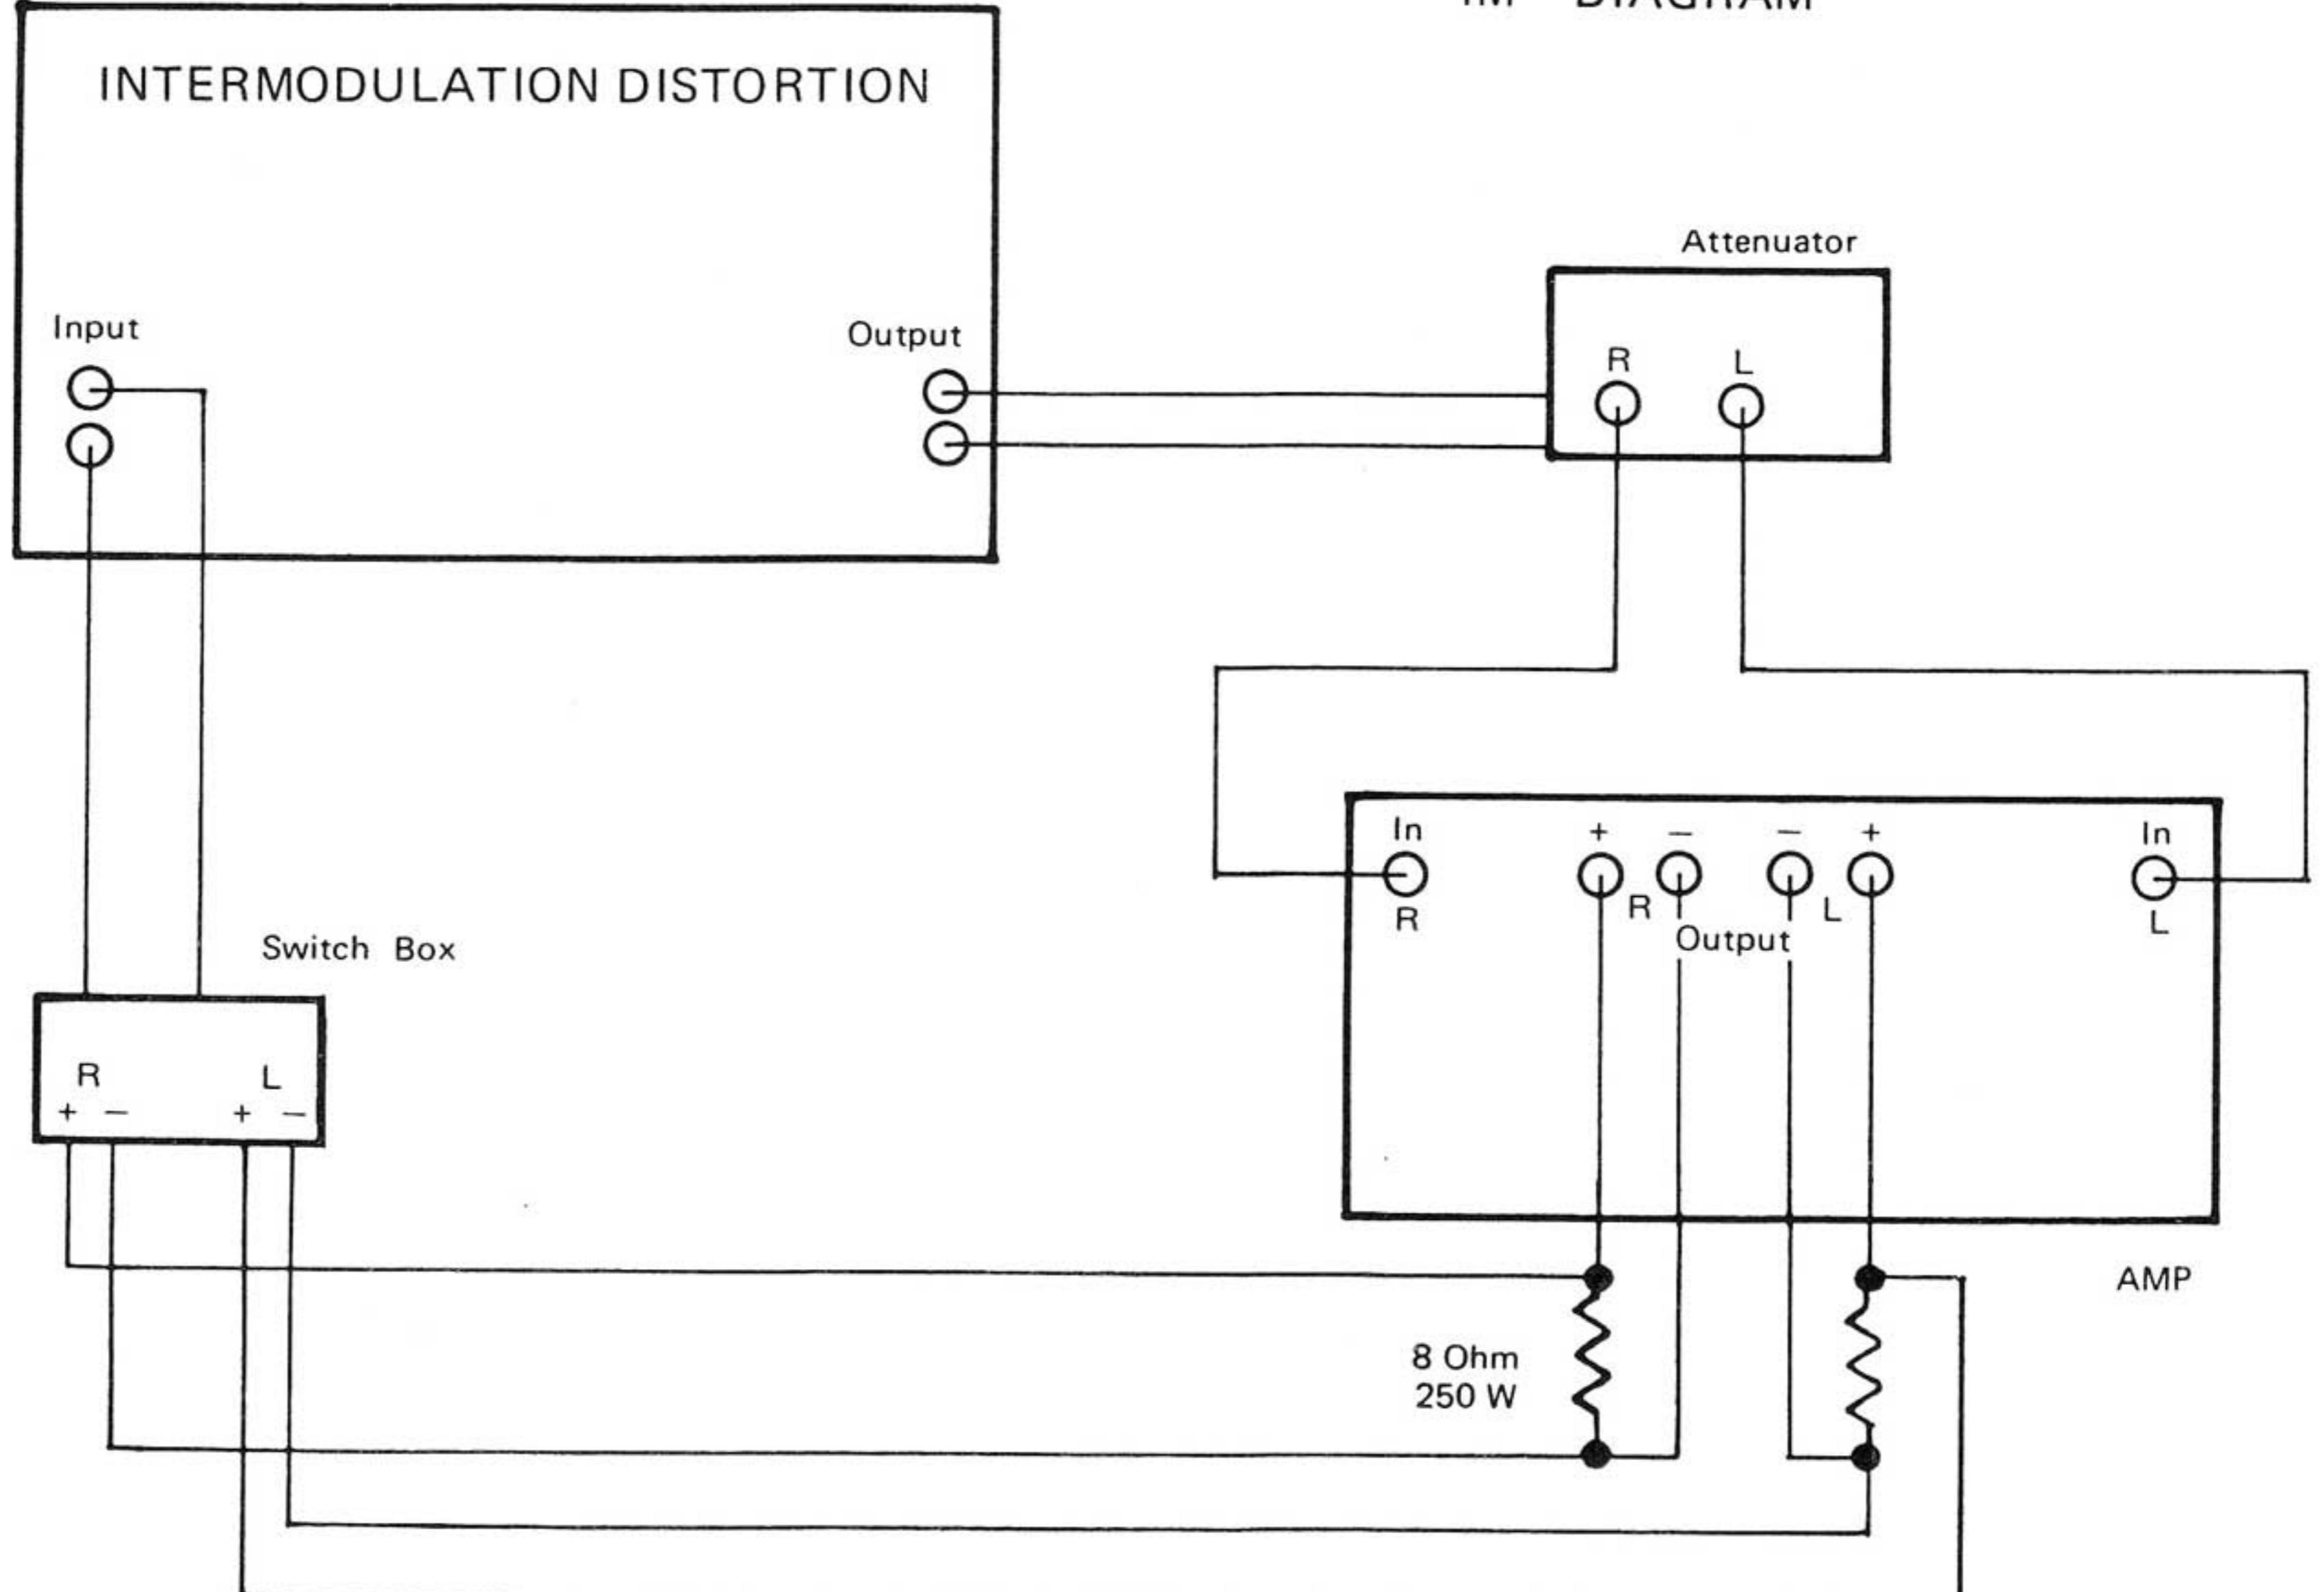

NOTE: Due to the extremely wide bandwidth of the amplifier, 200kHz R.F. fed directly into the inputs may destroy the output transistors. Therefore, under no circumstances, should the input cable be plugged into the Mark25/2500 input while the amplifier is operated. Under no circumstances should the amplifiers be checked to ascertain if it is operating by touching the input lead with your finger. Your body acts as an efficient antenna and can transfer an excessive amount of R.F. to the amplifier.
